Warmup: Aggregate Analysis

Time Complexity

```
def full bfs(graph):
                  status = {node: 'undiscovered' for node in graph.nodes}
                  for node in graph.nodes:
                        if status[node] == 'undiscovered'
                              bfs(graph, node, status)
             def bfs(graph, source, status=None):
    """Start a BFS at `source`."""
                  if status is None:
                        status = {node: 'undiscovered' for node in graph.nodes}
                  status[source] = 'pending'
                  pending = deque([source])
                  # while there are still pending nodes
                  while pending:
               while pending:
    u = pending.popleft()
    for v in graph.neighbors(u):
        # explore edge (u,v)
        if status[v] == 'undiscovered':
            status[v] = 'pending'
            # append to right
                                                                                               Total : O(V+E)
⊕(v)
⊕(e)
                                   pending.append(v)
                        status[u] = 'visited'
```

Exercise

What is printed if we run a BFS starting at a?

```
while pending:
    u = pending.popleft()
    print(f'Popped {u}')
    for v in graph.neighbors(u):
        print(f'Exploring edge ({u}, {v})')
        # explore edge (u,v)
        ...
```

Answer

```
Popping a
Exploring edge (a, b)
                                Popping d
Exploring edge (a, c)
                                Exploring edge (d, b)
Popping b
                                Exploring edge (d, c)
                                Exploring edge (d. e)
Exploring edge (b, a)
Exploring edge (b, c)
                                Popping e
Exploring edge (b. d)
                                Exploring edge (e, c)
Popping c
                                Exploring edge (e, d)
Exploring edge (c, a)
                                Exploring edge (e, f)
Exploring edge (c, b)
                                Popping f
Exploring edge (c, d)
                                Exploring edge (f, e)
Exploring edge (c, e)
```

Aggregate Analysis

- During any one call to bfs:
 - Number of printed nodes: ?
 - Number of printed edges: ?
- In **aggregate** (over all calls):
 - ► Number of printed nodes: exactly |V|
 - ► Number of printed edges: exactly 2|E|

Time Complexity

Full BFS takes $\Theta(V + E)$

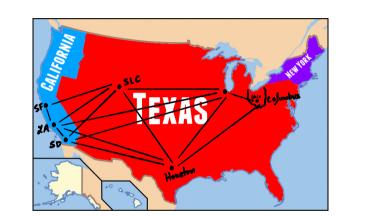

Time Complexity

- Full BFS takes $\Theta(V + E)$
- ▶ Why not just $\Theta(E)$?
- \triangleright $\Theta(V + E)$ works for all graphs.
 - If we know more about the number of edges, we might be able to simplify.
 - E.g., if the graph is **complete**, $E = \Theta(V^2)$, so time complexity is $\Theta(V + V^2) = \Theta(V^2)$.

Shortest Paths

Recall

► The **length** of a path is

(# of nodes) - 1

- A shortest path between u and v is a path between u and v with smallest possible length.
 - ► There may be several, or none at all.

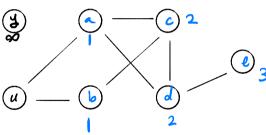

- ► The **shortest path distance** is the length of a shortest path.

 - Convention: ∞ if no path exists.
 "the distance between u and v" means spd.

Today: Shortest Paths

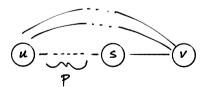

- ▶ **Given**: directed/undirected graph *G*, source *u*
- ► **Goal**: find shortest path from *u* to every other node

Example

Key Property

- ▶ A shortest path of length *k* is composed of:
 - A **shortest path** of length k − 1.
 Plus one edge.

Algorithm Idea

- Find all nodes distance 1 from source.
- Use these to find all nodes distance 2 from source.
- Use these to find all nodes distance 3 from source.
- ..

It turns out...

...this is exactly what BFS does.

Lecture 12 | Part 3

BFS for Shortest Paths

Key Property of BFS

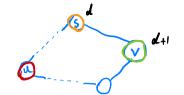

- For any $k \ge 1$ you choose:
- ► All nodes distance *k* 1 from source are added to the queue before any node of distance *k*.
- Therefore, nodes are "processed" (popped from queue) in order of distance from source.

Example

Discovering Shortest Paths

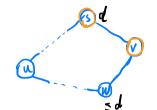

- We "discover" shortest paths when we pop a node from queue and look at its neighbors.
- But the neighbor's status matters!

Consider This

- We pop a node s.
- It has a neighbor v whose status is undiscovered.
- We've discovered a shortest path to v through s!

Consider This

- We pop a node s.
- It has a neighbor v whose status is pending or visited.

We already have a shortest path to v.

Modifying BFS

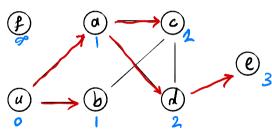

Use BFS "framework".

- Return dictionary of search predecessors.
 - If v is discovered while visiting u, we say that u is the BFS predecessor of v.
 - This encodes the shortest paths.
- Also return dictionary of shortest path distances.

```
def bfs shortest paths(graph, source):
    """Start a BES at `source`."""
    status = {node: 'undiscovered' for node in graph.nodes}
    distance = {node: float('inf') for node in graph.nodes}
    predecessor = {node: None for node in graph.nodes}
    status[source] = 'pending'
    distance[source] = 0
    pending = deque([source])
    # while there are still pending nodes
   while pending:
        u = pending.popleft()
        for v in graph.neighbors(u):
            # explore edge (u.v)
            if status[v] == 'undiscovered':
                status[v] = 'pending'
                distance[v] = distance[u] + 1
                predecessor[v] = u
                # append to right
                pending.append(v)
        status[u] = 'visited'
    return predecessor, distance
```

dt (v) dt

BFS Trees

Result of BFS

- ► Each node reachable from source has a single BFS predecessor.
 - Except for the source itself.
- ► The result is a **tree** (or forest).

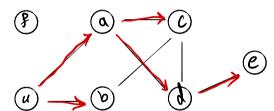

Trees

- A (free) tree is an undirected graph T = (V, E) such that T is connected and |E| = |V| 1.
- A forest is graph in which each connected component is a tree.

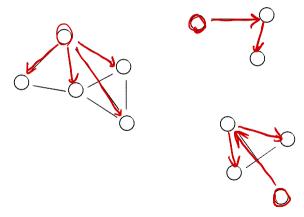

BFS Trees (Forests)

- ▶ If the input is connected, BFS produces a **tree**.
- If the input is not connected, BFS produces a forest.

Example

Example

BFS Trees

BFS trees and forests encode shortest path distances.
