Lecture 16 | Part 1

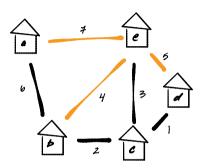

Minimum Spanning Trees

Today's Problem

- Choose a set of dirt roads to pave so that:
 - can get between any two buildings only on paved roads;
 - total cost is minimized.
- ► Solution: compute a minimum spanning tree.

Today's Problem

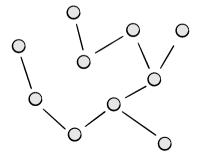

- Choose a set of dirt roads to pave so that:
 - can get between any two buildings only on paved roads;
 - total cost is minimized.
- ► Solution: compute a minimum spanning tree.

An undirected graph T = (V, E) is a tree if

- ▶ it is connected; and
- ▶ it is acyclic.

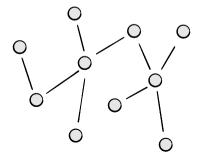

Example: a tree.

An undirected graph T = (V, E) is a tree if

- ▶ it is connected; and
- ▶ it is acyclic.

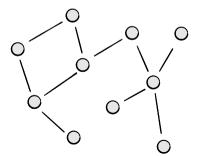

Example: a **tree**.

An undirected graph T = (V, E) is a tree if

- ▶ it is connected; and
- ▶ it is acyclic.

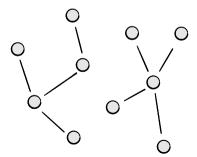

Example: **not** a tree.

An undirected graph T = (V, E) is a tree if

- ▶ it is connected; and
- ▶ it is acyclic.

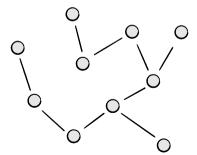

Example: **not** a tree.

An undirected graph T = (V, E) is a tree if

- it is connected; and
- |E| = |V| 1.

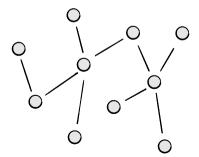

Example: a tree.

An undirected graph T = (V, E) is a tree if

- it is connected; and
- |E| = |V| 1.

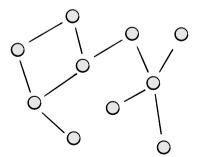

Example: a tree.

An undirected graph T = (V, E) is a tree if

- it is connected; and
- |E| = |V| 1.

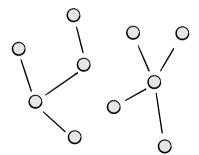

Example: **not** a tree.

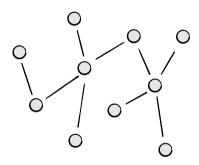

An undirected graph T = (V, E) is a tree if

- it is connected; and
- |E| = |V| 1.

Example: **not** a tree.

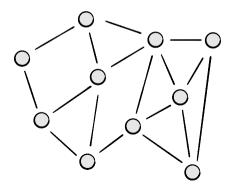

Tree Properties

- There is a unique simple path between any two nodes in a tree.
- Adding a new edge to a tree creates a cycle (no longer a tree).
- Removing an edge from a tree disconnects it (no longer a tree).

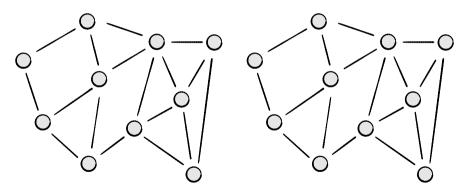

Spanning Trees

Let G = (V, E) be a **connected** graph. A **spanning tree** of G is a tree $T = (V, E_T)$ with the same nodes as G, and a subset of G's edges.

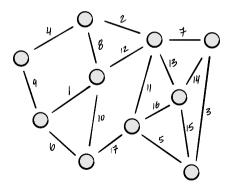

Many Spanning Trees

The same graph can have many spanning trees.

Spanning Tree Cost

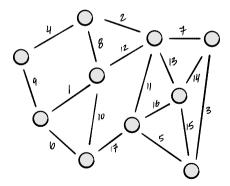

If $G = (V, E, \omega)$ is a weighted undirected graph, the **cost** (or **weight**) of a spanning tree is the total weight of the edges in the spanning tree.

Cost:

Spanning Tree Cost

Different spanning trees of the same graph can have different costs.

Cost:

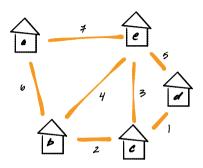

Minimum Spanning Tree

- ► The minimum spanning tree problem is as follows:
 - ► GIVEN: A weighted, undirected graph $G = (V, E, \omega)$.
 - COMPUTE: a spanning tree of G with minimum cost (i.e., minimum total edge weight).
- For a given graph, the MST may not be unique.

Exercise

Suppose the edges of a graph $G = (V, e, \omega)$ all have the same weight. How can we compute an MST of the graph?

Today's Problem

- Choose a set of dirt roads to pave so that:
 - can get between any two buildings only on paved roads;
 - total cost is minimized.
- ► Solution: compute a minimum spanning tree.

MSTs in Data Science?

- ▶ Do we need to find MSTs in data science?
- Actually, yes! (Next lecture)

Lecture 16 | Part 2

Prim's Algorithm

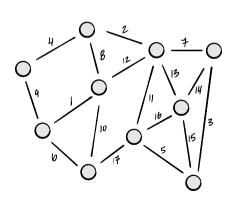

Building MSTs

- How do we build a MST efficiently?
- We'll adopt a greedy approach.
 - Build a tree edge-by-edge.
 - At every step, doing what looks best at the moment.
- This strategy isn't guaranteed to work in all of life's situations, but it works for building MSTs.

Two Greedy Approaches

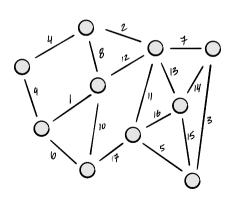

- We'll look at two greedy algorithms:
 - ► Today: Prim's Algorithm
 - Next time: Kruskal's Algorithm
- Differ in the order in which edges are added to tree.
- Also differ in time complexity.

Prim's Algorithm, Informally

- Start by picking any node to add to "tree". T.
- While T is not a spanning tree, greedily add lightest edge from a node in T to a node not in T.
 - "lightest" = edge of smallest weight

Prim's Algorithm, Informally

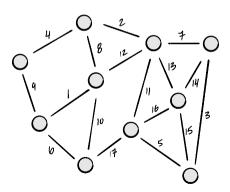

- Start by picking any node to add to "tree". T.
- While T is not a spanning tree, greedily add lightest edge from a node in T to a node not in T.
 - "lightest" = edge of smallest weight
- Is this guaranteed to work? Yes, as we'll see.

Prim's Algorithm, Equivalently

- For each node *u*, store:
 - estimated cost of adding node to tree;
 - estimated "predecessor" v in the tree.
- At each step,
 - Find node with smallest estimated cost.
 - Add to tree *T* by including edge with estimated "predecessor".
 - Update cost of neighbors.
- ► Same as adding lightest edge from *T* to outside *T* at every step!

Prim's Algorithm, Equivalently

- While T is not a tree:
 - find the node $u \notin T$ with smallest cost
 - add the edge between u and its estimated "predecessor" to T
 - update estimated cost/pred. of u's neighbors which aren't already in tree.

Recall: Priority Queues

- How do we efficiently find node with smallest cost?
- Priority Queues:
 - PriorityQueue(priorities): creates priority queue from dictionary whose values are priorities.
 - extract min(): removes and returns key with smallest value.
 - decrease_priority(key, value): changes key's value.
- We'll use a priority queue to hold nodes not yet added to tree.

```
def prim(graph, weight):
tree = UndirectedGraph()
estimated predecessor = {node: None for node in graph.nodes}
cost = {node: float('inf') for node in graph.nodes}
priority queue = PriorityQueue(cost)
while priority queue:
    u = priority_queue.extract min()
    if estimated predecessor[u] is not None:
        tree.add_edge(estimated_predecessor[u], u)
    for v in graph.neighbors(u):
        if weight(u, v) < cost[v] and v not in tree.nodes:</pre>
            priority queue.decrease priority(v. weight(u. v))
            cost[v] = weight(u. v)
            estimated predecessor[v] = u
return tree
```

Prim and Dijkstra

- This is a lot like Dijkstra's Algorithm for s.p.d.!
- ▶ Both: at each step, extract node with smallest cost, update its edges. (Prim: only those edges to nodes not in tree).
- ightharpoonup Dijkstra update of (u, v):

```
cost[v] = min(cost[v], cost[u] + weight(u, v))
```

 \triangleright Prim update of (u, v):

```
cost[v] = min(cost[v], weight(u, v))
```

DSC 40B Theoretical Foundations II

Lecture 16 | Part 3

- A priority queue can be implemented using a **heap**.
- ► If a **binary min-heap** is used:
 - PriorityQueue(est) takes Θ(V) time.
 - .extract_min() takes O(log V) time.
 - .decrease_priority() takes O(log V) time.

```
def prim(graph, weight):
tree = UndirectedGraph()
estimated_predecessor = {node: None for node in graph.nodes}
cost = {node: float('inf') for node in graph.nodes}
prioritv queue = PrioritvQueue(cost)
while priority_queue:
    u = priority queue.extract min()
    if estimated predecessor[u] is not None:
        tree.add edge(estimated predecessor[u], u)
    for v in graph.neighbors(u):
        if weight(u, v) < cost[v] and v not in tree.nodes:</pre>
            priority_queue_decrease_priority(v, weight(u, v))
            cost[v] = weight(u. v)
            estimated predecessor[v] = u
return tree
```

- Using a binary heap...
- ▶ Overall: $\Theta(V \log V + E \log V)$.
- Since graph is assumed connected, E = Ω(V).
- ▶ So this simplifies to $\Theta(E \log V)$.

Fibonacci Heaps

- A priority queue can be implemented using a **heap**.
- ► If a **Fibonacci min-heap** is used:
 - PriorityQueue(est) takes Θ(V) time.
 - extract_min() takes Θ(log V) time¹.
 - .decrease_priority() takes O(1) time.

¹Amortized.

```
def prim(graph, weight):
tree = UndirectedGraph()
estimated_predecessor = {node: None for node in graph.nodes}
cost = {node: float('inf') for node in graph.nodes}
prioritv queue = PrioritvQueue(cost)
while priority_queue:
    u = priority queue.extract min()
    if estimated predecessor[u] is not None:
        tree.add edge(estimated predecessor[u], u)
    for v in graph.neighbors(u):
        if weight(u, v) < cost[v] and v not in tree.nodes:</pre>
            priority_queue_decrease_priority(v, weight(u, v))
            cost[v] = weight(u. v)
            estimated predecessor[v] = u
return tree
```

- Using a Fibonacci heap...
- ▶ Overall: $\Theta(V \log V + E)$.

Fibonacci vs. Binary Heaps

- Using Fibonacci heaps improves time complexity when graph is dense.
- E.g., if $E = \Theta(V^2)$:
 - Prim's with Fibonacci: $\Theta(E) = \Theta(V^2)$
 - Prim's with binary: $\Theta(E \log E) = \Theta(V^2 \log V)$.
- But Fibonacci heaps are hard to implement; have large constants.
- Binary heaps used more in practice despite complexity.

Lecture 16 | Part 4

Correctness of Prim's Algorithm

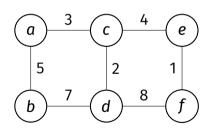

Being Greedy

- At every step, we add the lightest edge.
- ► Is this "safe"?

Being Greedy

- At every step, we add the lightest edge.
- ► Is this "safe"?
- Yes! This is guaranteed to find an MST.

Promising Subtrees

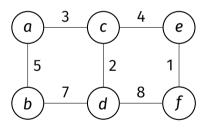

- Let G = (V, E, ω) be a weighted graph.
- A subgraph T' = (V', E') is **promising** if it is "part" of some MST.
 - That is, it is an "MST in progress"
 - Not necessarily a tree!
- That is, there exists an MST $T = (V, E_{mst})$ such that $E' \subset E_{mst}$.
 - Hint: a "promising subtree" where V' = V is an MST!

Main Idea

Prim's starts with a promising subtree T. At each step, adds lightest edge from a node within T to a node outside of T.

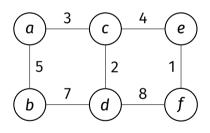

We'll show each new edge results in a larger promising subtree. Eventually the promising subtree becomes a full MST.

Claim

- Let $G = (V, E, \omega)$ be a weighted graph.
- Suppose T' = (V', E') is a promising subtree for an MST of G.
- Let e = (u, v) be a lightest edge from a node in T' to a node outside of T'. (Prim).
- Then adding (u, v) to T' results in another **promising subtree**.

Proof

- Suppose T_{mst} is an MST that includes T'.
- If T_{mst} includes e, we're done: T' + e is promising.
- If it doesn't include *e*, it must have an edge *f* that connects *T'* to rest of the graph.
- Swap f with e in T_{mst} . The result is a tree, and it must be a MST since $\omega(e) \le \omega(f)$.
- \triangleright So there is an MST that contains T' + e.
