

CS-GY 6923: Lecture 4

Continue on Bayesian Perspective, Modeling Language

NYU Tandon School of Engineering, Akbar Rafiey

- First written problem set due next Wednesday Feb. 19.
 - I will hold a Zoom office hour for the homework.
 - We will release solutions and go over them in office hours.
- Lab 3 was released yesterday, due on Feb 26.

Recap: probabilistic modeling

In a Bayesian or Probabilistic approach to machine learning we always start by conjecturing a

probabilistic model

that plausibly could have generated our data.

- The model guides how we make predictions.
- The model typically has unknown parameters $\vec{\theta}$ and we try to find the most reasonable parameters based on observed data.

Recap: spam prediction

Recap: email model

Include each word in an email with some fixed probability. That probability will differ depending on whether or not it is a spam or regular email.

Not Spam

$$p_{\text{won},0} = .02$$

$$p_{\$,0} = .05$$

$$p_{\text{student},0} = .06$$

Spam

$$p_{\text{won},1} = .1$$

$$p_{\$,1} = .2$$

$$p_{\text{student},1} = .01$$

Recap: probabilistic model for email

Probabilistic model for (bag-of-words, label) pair (\mathbf{x}, y) :

- Set $y = 0$ (not spam) with probability p_0 and $y = 1$ (spam) with probability $p_1 = 1 - p_0$.
 - p_0 is probability an email is not spam (e.g. 99%).
 - p_1 is probability an email is spam (e.g. 1%).
- If $y = 0$, for each i , set $x_i = 1$ with prob. p_{i0} .
- If $y = 1$, for each i , set $x_i = 1$ with prob. p_{i1} .

Unknown model parameters:

- p_0, p_1 ,
- $p_{10}, p_{20}, \dots, p_{d0}$, one for each of the d vocabulary words.
- $p_{11}, p_{21}, \dots, p_{d1}$, one for each of the d vocabulary words.

Recap: parameter estimation

Reasonable way to set parameters:

- Set p_0 and p_1 to the empirical fraction of not spam/spam emails.
- For each word i , set p_{i0} to the empirical probability word i appears in a non-spam email.
- For each word i , set p_{i1} to the empirical probability word i appears in a spam email.

Done with modeling
on to prediction

Probability review

- **Probability:** $p(x)$ – the probability event x happens.
- **Joint probability:** $p(x,y)$ – the probability that event x and event y happen.
- **Conditional Probability** $p(x | y)$ – the probability x happens given that y happens.

$$\begin{aligned} \rightarrow p(x,y) &= p(x) \cdot p(y|x) \\ \rightarrow p(x,y) &= p(y) \cdot p(x|y) \quad p(x|y) = \frac{p(y|x)p(x)}{p(y)} \quad \checkmark \end{aligned}$$

Classification rule

Given unlabeled input $(\mathbf{w}, \text{---})$, choose the label $y \in \{0, 1\}$ which is most likely given the data. Recall $\mathbf{w} = [0, 0, 1, \dots, 1, 0]$.

Classification rule: maximum a posterior (MAP) estimate.

Step 1. Compute:

- $p(y = 0 \mid \mathbf{w})$: prob. $y = 0$ given observed data vector \mathbf{w} .
- $p(y = 1 \mid \mathbf{w})$: prob. $y = 1$ given observed data vector \mathbf{w} .

Step 2. Output: 0 or 1 depending on which probability is larger.

$p(y = 0 \mid \mathbf{w})$ and $p(y = 1 \mid \mathbf{w})$ are called **posterior** probabilities.

Evaluating the posterior

How to compute the posterior? **Bayes rule!**

$$p(y = 0 | \mathbf{w}) = \frac{p(\mathbf{w} | y = 0)p(y = 0)}{p(\mathbf{w})} \quad (1)$$

$$\text{posterior} = \frac{\text{likelihood} \times \text{prior}}{\text{evidence}} \quad (2)$$

- **Prior:** Probability in class 0 prior to seeing any data.
- **Posterior:** Probability in class 0 after seeing the data.

Evaluating the posterior

Goal is to determine which is larger:

$$p(y = 0 | \mathbf{w}) = \frac{p(\mathbf{w} | y = 0)p(y = 0)}{\cancel{p(\mathbf{w})}} \quad \text{vs.}$$
$$p(y = 1 | \mathbf{w}) = \frac{p(\mathbf{w} | y = 1)p(y = 1)}{\cancel{p(\mathbf{w})}}$$

- We can ignore the evidence $p(\mathbf{w})$ since it is the same for both sides!
- $p(y = 0)$ and $p(y = 1)$ already known (computed from training data). These are our computed parameters p_0, p_1 .
- $p(\mathbf{w} | y = 0)$ = ? $p(\mathbf{w} | y = 1)$ = ?

Evaluating the posterior

Consider the example $\mathbf{w} = [0, 1, 1, 0, 0, 0, 1, 0]$.

Recall that, under our model, index i is 1 with probability p_{i0} if we are not spam, and 1 with probability p_{i1} if we are spam .

$$p(\mathbf{w} \mid y = 0) =$$

$$p(\mathbf{w} \mid y = 1) =$$

Naive bayes classifier

Training/Modeling: Use existing data to compute:

- $p_0 = p(y = 0), p_1 = p(y = 1)$
- For all i compute:
 - $p_{i0} = p(w_i = 1 | y = 0)$ and $(1 - p_{i0}) = p(w_i = 0 | y = 0)$
 - $p_{i1} = p(w_i = 1 | y = 1)$ and $(1 - p_{i1}) = p(w_i = 0 | y = 1)$

Prediction:

- For new input \mathbf{w} :
 - Compute $p(\mathbf{w} | y = 0) = \prod_i p(w_i | y = 0)$
 - Compute $p(\mathbf{w} | y = 1) = \prod_i p(w_i | y = 1)$
- Return $y = 0$ if
$$p(\mathbf{w} | y = 0) \cdot p(y = 0) \geq p(\mathbf{w} | y = 1) \cdot p(y = 1)$$
- Return $y = 1$ otherwise

**Other applications of
the bayesian perspective on regression**

Bayesian regression

The Bayesian view offers an interesting alternative perspective on many machine learning techniques.

Example: Linear Regression.

Probabilistic model:

$$y = \langle \mathbf{x}, \beta \rangle + \eta$$

Handwritten red annotations: a circle around β and an arrow pointing to the word "true" written in red above it.

where the η drawn from $N(0, \sigma^2)$ is **random Gaussian noise**.

$$\Pr(\eta = z) \sim e^{-z^2}$$

The symbol \sim means “is proportional to”.

Illustration

Example: Linear Regression.

Probabilistic model:

$$y = \langle \mathbf{x}, \boldsymbol{\beta} \rangle + \eta$$

where the η drawn from $N(0, \sigma^2)$ is **random Gaussian noise**. The noise is independent for different inputs $\mathbf{x}_1, \dots, \mathbf{x}_n$.

Gaussian distribution refresher

Names for same thing: Normal distribution, Gaussian distribution, bell curve.

Parameterized by **mean μ** and **variance σ^2** .

η is a continuous random variable, so it has a probability density function $p(\eta)$ with $\int_{-\infty}^{\infty} p(\eta) d\eta = 1$

$$p(\eta) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\eta-\mu}{\sigma}\right)^2}$$

Gaussian distribution refresher

The important thing to remember is that the the PDF falls off exponentially as we move further from the mean.

The normalizing constant in front $1/2$, etc. don't matter so much.

How should we select β for our model?

Also use a Bayesian approach!

First thought: choose β to maximize:

$$\text{posterior} = \Pr(\beta \mid \mathbf{X}, \mathbf{y}) = \frac{\Pr(\mathbf{X}, \mathbf{y} \mid \beta) \Pr(\beta)}{\Pr(\mathbf{X}, \mathbf{y})} = \frac{\text{likelihood} \times \text{prior}}{\text{evidence}}.$$

But in this case, we don't have a prior – no values of β are inherently more likely than others.

Choose β to maximize just the likelihood:

$$\frac{\Pr(\mathbf{X}, \mathbf{y} \mid \beta) \Pr(\beta)}{\Pr(\mathbf{X}, \mathbf{y})} = \frac{\text{likelihood} \times \text{prior}}{\text{evidence}}.$$

This is called the **maximum likelihood estimate**.

Fixed design linear regression

- Often we think of \mathbf{X} as fixed and deterministic, and only \mathbf{y} is generated at random in the model. This is called the fixed design setting.
- We can also consider a randomized design setting, but it is slightly more complicated.
- In the fixed design setting our task of maximizing $\Pr(\mathbf{X}, \mathbf{y} \mid \beta)$ simplifies to maximizing

$$\max_{\beta} \Pr(\mathbf{y} \mid \beta)$$

Maximum likelihood estimate

Data:

$$\langle \mathbf{x}_i, \beta \rangle + \eta_i = y_i \Rightarrow \eta_i = y_i - \langle \mathbf{x}_i, \beta \rangle$$

$$\mathbf{X} = \begin{bmatrix} - & \mathbf{x}_1 & - \\ - & \mathbf{x}_2 & - \\ & \vdots & \\ - & \mathbf{x}_n & - \end{bmatrix}_{n \times d} \quad \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_d \end{bmatrix}_{d \times 1} \quad \mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}_{n \times 1}$$

Model: $y_i = \langle \mathbf{x}_i, \beta \rangle + \eta_i$ where $p(\eta_i = z) \sim e^{-z^2/2\sigma^2}$ and η_1, \dots, η_n are independent. $\rightarrow e^{-\frac{(y_i - \langle \mathbf{x}_i, \beta \rangle)^2}{2\sigma^2}}$

Exercise:

$$\Pr(\mathbf{y} | \beta) \sim \prod_{i=1}^n e^{-\frac{(y_i - \langle \mathbf{x}_i, \beta \rangle)^2}{2\sigma^2}}$$
$$\Pr(y_i | \beta) = \Pr(\eta_i = \overbrace{y_i - \langle \mathbf{x}_i, \beta \rangle}^z) = e^{-\frac{(y_i - \langle \mathbf{x}_i, \beta \rangle)^2}{2\sigma^2}}$$

Log likelihood

$$f(x) > g(x) \Rightarrow \log(f(x)) > \log(g(x))$$

Easier to work with the **log likelihood**:

$$\arg \max_{\beta} \Pr(\mathbf{X}, \mathbf{y} \mid \beta) = \arg \max_{\beta} \prod_{i=1}^n e^{-(y_i - \langle \mathbf{x}_i, \beta \rangle)^2 / 2\sigma^2}$$

$$= \arg \max_{\beta} \log \left(\prod_{i=1}^n e^{-(y_i - \langle \mathbf{x}_i, \beta \rangle)^2 / 2\sigma^2} \right)$$

$$= \arg \max_{\beta} \sum_{i=1}^n -(y_i - \langle \mathbf{x}_i, \beta \rangle)^2 / 2\sigma^2$$

$$= \arg \min_{\beta} \sum_{i=1}^n (y_i - \langle \mathbf{x}_i, \beta \rangle)^2$$

$$\arg \min_{\beta} \sum_{i=1}^n |y_i - \langle \mathbf{x}_i, \beta \rangle| = \|\mathbf{y} - \mathbf{X}\beta\|$$

$$\arg \max_x f(x)$$

$$= \arg \max_x \log(f(x))$$

$$\log a \cdot b = \log a + b$$

$$\log a^b = b \log a$$

Conclusion: Choose β to minimize:

$$\sum_{i=1}^n (y_i - \langle \mathbf{x}_i, \beta \rangle)^2 = \|\mathbf{y} - \mathbf{X}\beta\|_2^2.$$

This is a completely different justification for squared loss!

Minimizing the ℓ_2 loss is “optimal” when you assume your data follows a linear model with i.i.d. Gaussian noise.

Bayesian regression

If we had modeled our noise η as Laplace noise, we would have found that minimizing $\|\mathbf{y} - \mathbf{X}\beta\|_1$ was optimal.

$$Pr(\eta = z) \sim e^{-|z|}$$

Laplace noise has “heavier tails”, meaning that it results in more outliers.

This is a completely different justification for ℓ_1 loss.

Bayesian regularization

- We can add another layer of probabilistic modeling by also assuming β is random and comes from some distribution, which encodes our prior belief on what the parameters are.
- Recall **Maximum a posteriori (MAP estimation)**:

$$\Pr(\beta \mid \mathbf{X}, \mathbf{y}) = \frac{\Pr(\mathbf{X}, \mathbf{y} \mid \beta) \Pr(\beta)}{\Pr(\mathbf{X}, \mathbf{y})}.$$

- Assume values in $\beta = [\beta_1, \dots, \beta_d]$ come from some distribution.
- What is a common model?

Bayesian regularization

- **Common model:** Each β_i drawn from $N(0, \gamma^2)$, i.e. normally distributed, independent.
- Encodes a belief that we are unlikely to see models with very large coefficients.

Goal: choose β to maximize:

$$\Pr(\beta \mid \mathbf{X}, \mathbf{y}) = \frac{\Pr(\mathbf{X}, \mathbf{y} \mid \beta) \Pr(\beta)}{\Pr(\mathbf{X}, \mathbf{y})}.$$

Bayesian regularization

Goal: choose β to maximize:

$$\Pr(\beta \mid \mathbf{X}, \mathbf{y}) = \frac{\Pr(\mathbf{X}, \mathbf{y} \mid \beta) \Pr(\beta)}{\Pr(\mathbf{X}, \mathbf{y})}.$$

- We can still ignore the “evidence” term $\Pr(\mathbf{X}, \mathbf{y})$ since it is a constant that does not depend on β .

- $\Pr(\beta) = \Pr(\beta_1) \cdot \Pr(\beta_2) \cdot \dots \cdot \Pr(\beta_d)$

- If each β_i drawn from $N(0, \gamma^2)$, $\Pr(\beta) \sim ?$

$$\prod_{i=1}^d e^{-\beta_i^2 / 2\gamma^2}$$

Bayesian regularization

Easier to work with the **log likelihood**:

$$1 \quad \arg \max_{\beta} \Pr(\mathbf{X}, \mathbf{y} \mid \beta) \cdot \Pr(\beta)$$

$$2 \quad = \arg \max_{\beta} \prod_{i=1}^n e^{-(y_i - \langle \mathbf{x}_i, \beta \rangle)^2 / 2\sigma^2} \cdot \prod_{i=1}^d e^{-(\beta_i)^2 / 2\gamma^2}$$

$$3 \quad = \arg \max_{\beta} \sum_{i=1}^n -(y_i - \langle \mathbf{x}_i, \beta \rangle)^2 / 2\sigma^2 + \sum_{i=1}^d -(\beta_i)^2 / 2\gamma^2$$

$$4 \quad = \arg \min_{\beta} \sum_{i=1}^n (y_i - \langle \mathbf{x}_i, \beta \rangle)^2 + \frac{\sigma^2}{\gamma^2} \sum_{i=1}^d (\beta_i)^2$$

Choose β to minimize $\|\mathbf{y} - \mathbf{X}\beta\|_2^2 + \frac{\sigma^2}{\gamma^2} \|\beta\|_2^2$.

Completely different justification for ridge regularization!

Test your intuition: What modeling assumption justifies LASSO regularization: $\min \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_2^2 + \lambda\|\boldsymbol{\beta}\|_1$?

Modeling language

Generative ML

Key idea behind generative ML:

- Build a very good probabilistic model for your data.
- Use that model to generate realistic looking new data.

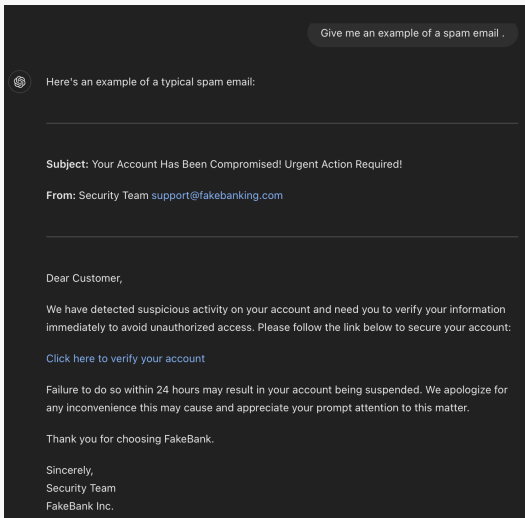

Example

Key idea behind generative ML: Build a very good probabilistic model for your data. Use that model to generate realistic looking new data.

Email example from our model: *Keeps retaining in astro associated to no garden superconducting whistleblower on effusion eigenvalue jobs worker for car shortlist villa depictions fitness the easter veto devices expressed secondary user metal this administrative the do of to struct coffee online cde the open through requirement stamps you job g thus drop stations.*

How do we go from this to something more like what modern models can produce?

Give me an example of a spam email .

Here's an example of a typical spam email:

Subject: Your Account Has Been Compromised! Urgent Action Required!

The color of the dress is ^a.
the

Autogressive models

Main issue: Our model lacks context!

The color of the dress is green.

Autogressive models

Key idea: Distribution that a word is chosen from should depend on previous words in the sentence/paragraph.

Consider generating a sentence with words x_1, x_2, \dots, x_n .

- Initialize the first word x_1 of the sentence (e.g. at random).
- Choose x_2 based on x_1 .
- Choose x_3 based on x_1, x_2, \dots .

Concretely, set $x_i = w$ with probability:

$$P(x_i = w \mid x_{i-1}, x_{i-2}, \dots, x_1).$$

Autoregressive models

Autoregressive model's generate text in order.

- How most humans write sentences, emails, short text.
- How the latest modern language models write text (e.g. the GPT family of models.)

This is not the only approach to generative modeling, but it is one that works fairly well in practice, especially for text.

Can also be used e.g. for images, but no longer state of the art.

Can also be used e.g. for images, but no longer state of the art.

Abstract

Modeling the distribution of natural images is a landmark problem in unsupervised learning. This task requires an image model that is at once expressive, tractable and scalable. We present a deep neural network that sequentially predicts the pixels in an image along the two spatial dimensions. Our method models the discrete probability of the raw pixel values and en-

Figure 1. Image completions sampled from a PixelRNN.

Figure 2. **Left:** To generate pixel x_i one conditions on all the previously generated pixels left and above of x_i . **Center:** To generate a pixel in the multi-scale case we can also condition on the subsampled image pixels (in light blue). **Right:** Diagram of the connectivity inside a masked convolution. In the first layer, each of the RGB channels is connected to previous channels and to the context, but is not connected to itself. In subsequent layers, the channels are also connected to themselves.

Autogressive models

Can also be used e.g. for images, but no longer state of the art.

$$p(x_i) = p(x_1)p(x_2 | x_1)p(x_3 | x_1, x_2) \dots p(x_i | x_1, x_2, \dots, x_{i-1})$$

$$p(x_i, \theta) = \prod_{j=1}^i p(x_j | x_1, \dots, x_{j-1}; \theta) \quad (\text{parametrize a model by } \theta)$$

Autoregressive models

Can also be used e.g. for images, but no longer state of the art.

$$p(x_j | x_1, \dots, x_{j-1}, \theta) = \theta_1 x_1 + \theta_2 x_2 + \dots + \theta_{j-1} x_{j-1}$$

$$p(x_i) = p(x_1) p(x_2 | x_1) p(x_3 | x_1, x_2) \dots p(x_i | x_1, x_2, \dots, x_{i-1})$$

$$p(x_i, \theta) = \prod_{j=1}^i p(x_j | x_1, \dots, x_{j-1}; \theta) \quad (\text{parametrize a model by } \theta)$$

$$\log p(x_i, \theta) = \sum_{j=1}^i \log p(x_j | x_1, \dots, x_{j-1}; \theta) \quad (\text{MLE})$$

Different architectures to model $p(x_j | x_1, \dots, x_{j-1}; \theta)$:

- Suggestion?

$$p(x_j | x_1, \dots, x_{j-1}) = \Pr(x_j | y^j)$$

$$p(x_j | x_1, \dots, x_{j-1}, \theta) = \theta_1 x_1 + \theta_2 x_2^2 + \theta_3 x_3^3 + \dots + \theta_{j-1} x_{j-1}^{j-1}$$

Autogressive models

Different architectures to model $p(x_j | x_1, \dots, x_{j-1}; \theta)$:

- Convolutional Models (PixelCNN)
- Recurrent Models (PixelRNN)
- Transformer-based Models (ImageGPT, GPT)
- All of the above approaches need good (semantic) word embeddings. We will learn about this later in the course.
- Today: simple model and simple complexity

Limited lookback

Key idea: Distribution that a word is chosen from should depend on previous k words in the sentence/paragraph. k is a parameter that controls model complexity.

Limited lookback

Key idea: Distribution that a word is chosen from should depend on previous **k words** in the sentence/paragraph. k is a parameter that controls model complexity.

Consider generating a sentence with words x_1, x_2, \dots, x_n .

- Initialize the first k word x_1, \dots, x_k of the sentence (e.g. at random).
- Choose x_{k+1} based on x_1, \dots, x_k .
- Choose x_{k+2} based on x_2, \dots, x_{k+1} .
- Choose x_{k+3} based on x_3, \dots, x_{k+2} .
- ...

Set $x_i = w$ with probability:

$$P(x_i = w \mid x_{i-1}, x_{i-2}, \dots, x_{i-k}).$$

Probabilistic model

Set $x_i = w$ with probability:

$$P(x_i = w \mid x_{i-k}, \dots, x_{i-2}, x_{i-1}).$$

This probability can be tractably estimate from our data!

It is exactly the same as the probability of observing the $k + 1$ -gram $[x_{i-k}, \dots, x_{i-2}, x_{i-1}, w]$.

Training:

- For corpus of text, collect all $k + 1$ -grams and record their frequency. (not much optimization involved!)

Prediction:

- At step i , sample from the subset of $k + 1$ grams starting with $[x_{i-k}, \dots, x_{i-2}, x_{i-1}]$, with probability proportional to their frequency.

Example

x_{i-6} x_{i-5} x_{i-4} x_{i-3} x_{i-2} x_{i-1} x_i
The color of the dress is red.

- Reasonable completions for $k = 2$:

"dress is red"

"is dress red"

"red is dress"

$\left[\begin{array}{c} 3 \\ 2 \end{array} \right]$

- Reasonable completions for $k = 5$:

"dress is large"

"large is dress"
